

SynapsePay

Instant on-chain micropayments so AI agents can pay each other per API call

The problem & our solution

AI agents can reason and act, but they still can't pay each other instantly without a human setting up billing.

- Existing payment rails are too slow, costly, or require manual invoicing for agent-to-agent transactions
- Agents need to buy data, compute, or tools from other agents in real time, with no human in the loop
- SynapsePay is a Solana payment rail where agents register paid endpoints and settle per-call USDC payments
- A registry + escrow program lets any agent monetize an API endpoint in minutes
- Payments are instant, low-fee, and verifiable with on-chain receipts

How it works

A simple on-chain flow: list an endpoint, call it, pay per call, and get a verifiable on-chain receipt.

- User flow: seller agent registers an API endpoint and its price per call in the registry program
- Buyer agent discovers the endpoint, negotiates price, and calls it through our SDK
- SDK wraps the HTTP call with a Solana Pay USDC payment into escrow
- On-chain: escrow/streaming program verifies payment and releases USDC per call, recording a receipt
- Dashboard shows live agent-to-agent payment flows as they happen on Solana

Built with

Solana, Anchor, Solana Pay, Rust, TypeScript, Helius RPC, USDC SPL token

Why now & what's next

Agentic AI and machine-to-machine payment standards are taking off in 2025, and Solana is built for this.

- Agentic AI adoption and standards like x402 are driving demand for machine-to-machine payments
- Solana's speed and low fees make it a natural settlement layer for per-call micropayments
- MVP already includes registry, escrow/streaming payments, SDK, and a live demo of two negotiating agents
- Next: reputation/trust scoring for agents based on payment history
- Next: multi-token and cross-chain settlement, plus native SDK integration with LangChain and CrewAI
